### (57) ABSTRACT

A method and system for implementing policy by accumulating policies for a policy recipient from policy objects associated with a hierarchically organized structure of containers, such as directory containers (sites, domains and organizational units) that includes the policy recipient. Based on administrator input, policy settings for the policy recipient may be accumulated into a specific order by inheriting policy from higher containers, which may enforce their policy settings over those of lower containers. Policy that is not enforced may be blocked at a container. Fig. result is an accumulated set of group policy objects that are ordered by relative succepts to resolve any policy conflicts. Policy may be applied to a policy recipient by calling extensions, such as an extension that layers the policy settings into the registry or an extension that nees policy information from the objects according to the ordering thereof. Linking of group pulicy objects to one or more containers (e.g., sites, domains and organizational units) is provided, as is exception management. The effects of group policy may be littered based on users, or computers' membership in security groups.

### SYSTEM AND METHOD FOR IMPLEMENTING GROUP POLICY

The present application is a continuation-in-part of U.S. patent application Ser. No. 99/134/805 entitled "System and Method for Implementing Group Policy," filed on Aug. 14, 1998 now abundanced.

#### FIELD OF THE INVENTION

The invention relates generally to computer systems and a networks, and more particularly to an improved method and system for implementing policy for users and computers.

### BACKGROUND OF THE INVENTION

Lost productivité at amplioyecs' computar desktops is a rapique cost for coperations, other resulting from some enteres such as meditying system configuration files in ways that render his conjugiter unworlatible. Perductivity is also lost when a computer desktop is too complex, such as when the desktop has too many non-costnal applications and features thereon. At the same lime, much of the expense of administration distributed personal computer according to a computer according to the configuration of the configuration of the desktop has the configuration of computer according to the configuration of the configuration of the desktop has been also according to the loss than inswerethy or indivertially modification.

As a result, enterprises such as corporations have established policies seeking to define settings for computer users. For example, a corporation may wish to have the same e-mail and word processing program on all their users' desktops, while certain users such as those in the engineering group have a common CAD program not available to users in the hoance group. Another policy may selectively prevent a user from connecting to the Internet by writing information into the user's machine registry to prevent arcess. Centralized policy systems exist to allow an administrator some control over the settings that institute such policies, and provide benefits in scalability to assist in the administration of larger networks. For example, in networks prespized into domains, (such as with Microsoft® Windows NT00-4.0), such policies may be applied per domain, based as on each domain user's membership in a scentity group

However, there are a mumber of drawbacks present with existing policy systems. One such drawback is that the policies are essentially static, whereby a user can change the settings and simply avoid the policy. It is cost prohibitive to as have an administrator of the like go from machine to machine to check the settings on a regular basis. It is nossible to force mandatory profiles on a user at each log-on based on the user's group membership. However such mandatory profiles are too inflexible, in that essentially all so settings made by an individual user are lost whenever the user logs off. For example, with mandatory profiles, cus topizations to a desktop, such as window placement, adding words to a user's spell checker and the like, which most emerprises would consider pentissible and even desirable 35 because they tend to increase an employee's efficiency, are test when the user logs off

Another segnificant devolvade, results from relying our ascentify group membership to determine the settings, particularly the new group (the first group found for a user) as membership to the segnificant form of the first group found to a user) as ground the employment and formular groups, the user will get muly one set of policy settings. Present policy determination systems, such as those besting policy on the domain plus monthership in a security group, escentally 85 follows 4 far model, which does not fit well with a typical enterprise having a herarchical organizational starteture.

### 2

SUMMARY OF THE INVENTION Briefly, the present invention provides a system and method for implementing policy for users and computers. Policy settings are placed into group policy objects, and each of the policy objects may be associated with one or more containers, such as hierarchically-organized directory objects (containers), e.g., a domain, site or organizational unit. Based upon administrator input, settings from policy objects are accumulated and associated with a policy recipient, whereby users' computers and the like receive the accumulated policy. To accumulate policy, the settings of group policy objects associated with directory containers may be inherited, e.g., the group policy settings may be inherited from directory containers hierarchically above a policy recipient. The administrator may enforce inheritance no some of the policy objects and/or block the inheritance of policy objects associated with other containers. The admin istrator's input also orders the group policy objects, whereby any conflicts are resolved by the ordering precedence, i.e., the policy's relative strength. Policy may be applied to a recipient by layering the policy softings, based on the ordering, weakest first such that strongest settings overwrite weaker settings, or by seeking policy information from the strongest to weakest policy until the desired policy is located

A number of very Bexible conditions based on an Active Directory hierarchy may be included. By default, an object's parent container in the hierarchy is the strongest factor, but other containers to the parent may affect an object's policy, and by default, group policy affects each of the computers and users in a selected active directory container. A default inheritance evaluates group policy starting with the active directory container that is furthest away, whereby the Active Directory container closest to the computer or user has the ability to override policy set in a higher level container, in the order of Site, Domain, Organizational Unit or Units (SDOU) Moreover, there is provided an option to block inheritance of policy from higher patent containers, however there are also options that allow policy of a specific group policy object to be enforced so that group policy objects in lower level comminers cannot override the policy settings of higher level containers, i.e., an enforced option takes precedence. In addition, the effects of group policy may be filtered based on users or computers' membership in a seemily group

Other advantages will become apparent from the following detailed description when taken in commercion with the drawings, in which:

### BRIEF DESCRIPTION OF THE DRAWINGS

14G. I is a block diagram representing a computer system into which the present invention may be incorporated;

FIG. 2 is a block diagram generally representing exemplary components for implementing policy in accordance with various aspects of the present invention.

FIG. 3 is a block diagram generally illustrating hierarchical relationships between sites, domains organizational units and group policy objects of a network in accordance with me aspect of the present invention.

FIG. 4 is a block diagram representing how a user may fit under a number of hierarchically organized directory continers associated with group policy objects.

FIG. 5 is a representation of an exemplary over interface via which an administrator may associate group policy objects within the current Active Directory scopion.

FIG. 6 is a block diagram representing a user under hierarchically organized directory containers associated with group policy objects;

FIGS, 7A-7B comprise a flow diagram generally representing the steps taken to construct an ordered list of group policy objects for the user represented in FIG. 6 in accordance with one aspect of the present invention;

FIGS, 8A-8M are representations of lists of group policy objects being used to construct the ordered list of group policy objects in accordance with one aspect of the present essentiae.

FIG. 9 is the ordered list of group pulicy objects constructed for the user represented in FIG. 6 in accordance with one aspect of the present invention;

FIG. 10 is a flow diagram generally representing the steps taken to apply policy to a registry during policy update events (e.g., machine boot or user logon) based on an continued fists

under hierarchically organized directory containers associated with group policy objects wherein one of the organizational units is linked to another;

FIG. 12 is a block diagram representing how domains may receive enterprise policy, 14GS, 13A-13C represent some of the ways in which an

ordered list of group policy object may be changed and an extension notified of change information;

FIGS, 14A-14B comprise a flow diagram for determining a slow or fast link, including determining a data transfer rate, for changing how group policy may be applied; and

F(G. 15 is a block dargram representing how a user and a machine may lit under a number of hierarchically organized directory containers associated with group policy objects, and how those policy objects may be applied as depending on a mode setting.

### DETABLED DESCRIPTION OF THE PREFERRED EMBODIMENT

fixemplary Operating Invitorment FIG. I and the following discussion are intended to provide a brief general description of a suitable computing environment in which the invention may be implemented. Although not required, the invention will be described in the general context of computer executable instructions, such as 45 program modules, being executed by a personal computer. Generally, program modules include routines, programs, objects, components, data structures and the like that perform particular tasks or implement particular abstract data typus. Moreover, those skilled in the art will appreciate that the invention may be practiced with other computer system configurations, including hand-held devices, multiprocessin systems, microprocessor-based or programmable consumer electronics, network PCs, minscomputers, mainframe computers and the like. The invention may also be s practiced in distributed computing environments where tasks are performed by remote processing devices that are linked through a communications network, including for example, computers, network devices, and printers. In a distributed computing covironment, program modules may so he located in both local and remote memory storage devices.

With reference to FIG. 1, an exemplary system for implementing the invention includes a general purpose computing device in the form of a conventional personal commuter 20 or the like, including a processing unit 21, a system memory 65 22, and a system bus 23 that complex various system compagents including the system memory to the processing unit

21. The system bus 25 may be any of several types of bus structures including a memory bus or memory controller, a peripheral bus, and a local bus using any of a variety of bus architectures. The system memory includes read only memory (ROM) 24 and random access memory (RAM) 25. A basic input/output system 26 (BIOS), containing the basic routines that help to transfer information between elements within the personal computer 20, such as during start up, is stored in ROM 24. The personal computer 20 may further include a hard disk drive 27 for reading from and writing to a hard disk, not shown, a magnetic disk drive 28 for reading from or writing to a removable magnetic disk 29, and an optical disk drive 30 for reading from or writing to a removable optical disk 31 such as a CD-ROM or other optical media. The hard disk drive 27, magnetic disk drive 28, and optical disk drive 30 are connected to the system bus 23 by a hard disk drive interface 32, a magnetic disk drive interface 33, and an optical drive interface 34, respectively. The drives and their associated commuter readable media FIG. 11 is a block diagram representing how users may by 26 provide non-volunte storage of computer readable instructions, data sementres, program modules and other data for the personal company 20. Although the exemplary environment described herein employs a hard disk, a removable magnetic disk 29 and a removable optical disk 31, it should be appropriated by those skilled in the art that other types of computer readable media which can store data that is accessible by a computer, such as magnetic cassettes, flash memory eards, digital video disks, Bernoulli cantridges, random access memories (RAMs), read-only memories (ROMs) and the like may also be used in the exemplary precating cuvironment.

A number of program modules may be stored on the hard disk, magnetic disk 29, optical disk 31, ROM 24 or RAM 25, including an operating system 35 (preferably Windows/6 2000), one or more application programs 36, other program modules 37 and program data 38. A user may enter commands and information into the personal computer 20 through input devices such as a keyboard 40 and pointing device 42. Other input devices (not shown) may include a an microphone, joystick, game pad, satellite dish, seamer or the like. These and other input devices are often connected to the processing unit 21 through a serial post interface 46 that is compled to the system bus, but may be connected by other interfaces, such as a parallel port, game port or universal screat bas (USB). A monitor 47 or other type of display device is also connected to the system bus 23 year an interface, such as a volum adapter 48 In addition to the monitor 47, personal computers typically include other peripheral output devices (not shown), such as speakers and

printers. The personal computer 20 may operate in a networked environment using logical connections to one or more remote computers, such as a remote computer 49. The tennote computer 49 may be another personal computer, a server, a router, a network PC, a peer device of other common network node, and typically includes many or all of the elements described above relative in the personal computer 20, although only a memory storage device 50 bas been illustrated in FIG. 1. The logical connections depicted in FIG. 1 include a local area network (LAN) 51 and a wirle area network (WAN) 52. Such networking environments are commonplace in offices, caterprise-wide computer networks, Intranets and the Internet

When used in a I AN networking environment, the personal computer 20 is connected to the local network 51 through a network interface or adapter 53. When used to a WAN networking environment, the personal computer 20 typically includes a modem 54 or other means for establish-

ing communications over the wide area network 52, such as the Internet. The modern 54, which may be internal or external, is connected to the system bas 23 via the serial part interface 46. In a networked environment, program modules depicted relative to the personal computer 20, or portions thereof, may be stored in the remote memory storage device. It will be appreciated that the network connections shown are exemplary and other means of establishing a communications link between the computers may be used. For purposes of the following description, a network administrator may be using the computer system 20 to establish and implement group policies in accordance with the present invention, while users subject to the group policies connect to the network via the remote computers 49. Group Policy

In general, the present invention provides a method and vision for implementing policies throughout a network in a highly flexible, scalable, extensible and efficient manner. To this end, any container capable of having attributes may 26 have a group policy object attached thereto, and the group policy object may be evaluated to apply policy to policy recipients related to that container. For example, policy may he applied by specifying policy seitings in the group policy objects, including registry-based settings, scripts, (computer as registry sturtup and shutdown scripts, and user logon and logoff scripts), user documents and settings, application deployment, software installation, security settings and IP security. Indeed, policy objects may be extended to include virie dly any desired information, as long as a client-side (or other) extension that uses the policy object is capable of interpreting and/or handling the information therein. Note that a server-side process may act as the chent and interpret the policy, and pass the results to another client, e.g., a server-side extension may receive and process one or more 38 policy objects and transmit the results of its processing to a romer which then performs according to that policy.

In a preferred implementation described berein, the system and method utilize a highly flexible architecture of the for can link pulicies to containers which are hierarchically omanized directory objects representing sites, domains, organizational units and policy recipients (e.g., groups of users and computers) thereunder. Thus, although not necessary to the present invention, the group policy system and as method preferably utilize a Windows@ 2000 directory service, known as Active Directory 60 (of a domain con troller 62, FIG. 2), that stores information about the objects of a domain, and makes the information easy for administrators to access, lind and apply via a single, consistent and open set of interfaces. For example, with Active Directory, administrators can access resources anywhere on the network. Similarly, administrators have a single point of administration for the objects on the network, which can be viewed in a hierarchical structure. A core unit in the Active Direct 55 tory is the domain, and many of the objects of a network exist within a domain. A single domain can span multiple physical locations or sucs. Notwithstanding, although described herein with reference to Windowski 2000, the Active Directory, sales, domains, organizational units, and sit 160 both, the present invention is not limited thereto, not even to directory contamers in general, but rather is applicable to any containers capable of being linked to a policy object and having policy accumulated therefor.

editor 64 (a Microsoft Management Console snap-in or similar over interface), and these settings are ordinarily

manuained in a group policy object (GPO) such as 66 Group policy objects 66, 66, may store group policy information in locations including a group policy container and a group policy template. A group policy container is an Active Directory object that stores group policy object properties, and may include sub-containers for machine and user group policy information. Properties of a group policy container may include version information, which is used to custure that the information is synchronized with the group policy template information, status information, e.g., whether the group policy object is enabled or disabled, and a list of components (e.g., extensions) that have seltings in the group policy object. The group policy template is a folder structure preferably located in a system volume tolder is of the domain controller 62, and serves as the container primardy for tile-based information, (e.g., scripts). The policy information may include one or more pointers to another location (e.g., a data file on a SQL server) where some or all of the actual policy information (or a further pointer thereto) is maintained. Policy information also may be stored in a virtual registry (e.g., a copy of some or all of a client machine's registry maintained in a file on the server, specifically in the group policy template), that may be used by an extension to put information into the client-machine's

The group policy editor 64 or similar user interface tool (e.g., user interface 82) further allows an administrator to selectively associate the group policy objects with directory container objects 68, 68, (11G. 2) such as those shown in FIG. 3, i.e., domains 70, and 70, sites (e.g., site 72), and or organizational units 76, -76, A site comprises one of more ranges of 1P addresses of which computers can be a member. Organizational units are a type of directory object included within domains that are logical containers into which users, gamps, computers, and even other organizational units may be placed and hierarchically organized.

In accordance with aspects of the present invention, for each user of an organizational unit, the policy settings maintained in the policy objects 66, 66, may be selectively Windows@ 2000 operating system, in which an administra- as accumulated in an order of precedence, inherited from the group policy objects associated with one or more higher up organizational units 76,-76, the sac 72 and/or the domain (e.e., 70,), and/or blocked from being inherited. In general, in typical networks, the closer an organizational unit is to a user, the more likely that the administrator of that organizational unit will have a fair number of policies for that user Mid-level policies are less bleely to be present, and if present, are more likely to be suggested policy that may be blocked, as described below. Near the top of the lifement, very lew policies are likely, but those that are present will be most likely important and thus enforced. Thus, to accumulate policy in a pretented implementation, policies are applied in a reverse hierarchical order, and higher nonenforced policies may be blocked, however higher policies that are enforced take precedence by hierarchical order.

FIG. 4 generally shows the concept of accumulating policies, metading ordering (within a directory container). inheritance and the blocking of inheritance. In URL 4, users 80, that are members of organizational ann D (76,) have a Instatebacat claim of A. B. C and D. Such users may have policies accumulated from the group policy objects 66, 66, associated with containers as set by one or more administrators. In FIG. 4, the associations are shown by arrows from the directory containers A, B, C and/or D (70a, 76a, 76a) to Group policy settings may be created via a group policy of the group policy objects 66, 664. For example, a domain administrator may set properties such that the users will, by enforcement, inherit the policies from the group policy object or objects  $(66_1)$  associated with domain  $A(70_A)$  One or more administrators of the organizational units may set properties such that the users receive policies from group policy objects GPO3 (twice) and GPO4 (66 a 665, 664), and have inheritance blocked from the non-enforced group policy objects above, e.g., group policy object 66g associ ated with organizational and 8 (76n). The ability to order the group policy objects 66, and 66, within the directory container object (organizational unit D 76,) provides the administrator with a nucleousm for handling conflicting policies, if any, within a directory container. At the same time, the bicrarchy, in conjunction with enforcement and blocking options set by appropriate administrators, determine the final order among group policies applied to a user

To this end, as shown in FIG. 5, the administrator of a site, domain or organizational unit, is provided with a user interface 82 that essentially allows the administrator to configure the ordering of the group policy objects within the directory container, enforce selected policies (or not), and above. The administrator at each level intuitively sets these rankings such as by clicking bottons, checkboxes or the like, within Active Directory and site management tools, (e.g., Active Directory Sites And Services and/or Active Directory Users and Computers) For example, in FIG 5, the admin- 25 istrator may reorder the associated group pulicy objects, select "No Override," (i.e., "Enforce") for each of the group policy objects, and "Block" (via the blocking checkbox) those policy objects above that are not enforced. Policy policy, in that suggested policy can be blocked by settings in lower level directory container objects and the suggested policy settings essentially discarded. Where there is more than one group policy object associated with a directory container, the administrator of that directory container is (SDOU) may order the group policy objects therein to determine relative strengths of each. Thus, for example, (not shown), domain A may have associated policies ordered A1, A2, A3 and A4, although such internal rankings are not known to administrators of the lower mas, which see only as a unified "A" policy

With respect to FIG. 4, consider by way of example the chain A. B. C. D from highest directory container (object) to lowest, wherein the users 80, under organizational unit D may receive policies from group policy objects associated 44 with any or all of these containers. In the present example, for the users 80 , assume an administrator wants to have the policy object GPO1 (associated with the domain A) be the strongest, (in case of any conflict). One or more lower-level administrators (possibly the same administrator as the se domain administrator) want GPOT's policy to be followed by GPO3, followed by GPO3 again, then by GPO4, then by GPO2, and fastly by any policies associated with the local machine (which is also allowed).

The administrators can achieve the desired order by 85 enforcing domain A's associated group policy, ordering GPO3 above GPO4 within organizational unit D (76, 3, and not selecting any blocking. The result, provided by an ordering incchansin 88 (FIG. 2) as described below, is essentially an ordered list of group policy objects (from sa weakest to strongest) of Local Machine, GPO2, GPO4, GPO3, GPO3 and GPO1 (strongest because culoreed). The order determines how pattery is applied during policy update events, e.g., machine boot or user logon, and in what priority policy is applied if there is a conflict. Note that the actual policy that results from applying one group policy object may depend on what occurred when a group policy object

was previously applied. For example, a group policy object may act one way if a script has been previously run, and another way if the script was not previously run. As a result, the same group policy object may have different results for different users, depending on whether another group policy object which turns that script was previously applied in a given user. Further, note that a group policy object may influence its own actions it applied more than once to a user, e.g., GPO3 may be applied twice in the example shawn in

FIG. 4, and thus, for example, may do some action the first time that changes how GPO3 acts the second time.

FIGS 5 through 9 provide an explanation of a soutable modianism 88 (FIG. 2) and process therein for developing an ordered list 90 based on the choices selected by the administrator via the user interface 82 (such as the interface shown in FIG. 5). In FIG. 6, the user is under a Site S1. Domain A, and organizational units OU1 and OU2. In FIG. 6, arrows from the directory containers to the group policy objects show each of the associations, which are actually block inhoritance (or not) of non-enforced policy objects to maintained as properties of the directory containers. Thus, the site S1 is associated with group policy object GPO1, the Domain A is associated with group policy objects GPO1. GPO2 and GPO3, while the organizational unit OUI has no group policy objects associated therewith. The organizational unit OU2 has group policy objects GPO3, GPO4, GPO5 and GPO6 associated therewith. If more than one group policy object is associated with an organizational unit. a prioritized ordering of the group policy objects is also established, for purposes of simplicity, in FIG, 6, the higher injects that are not enforced may be considered suggested to a group policy object appears, the stronger it is relative to others associated with the same directory container. For example, with respect to organizational unit OU2, via the interface 82 (FIG. 5), the administrator has set GPO3 to be stronger than GPO4, which in turn is stronger than GPO5. and these are stronger than GPO6. Note, however, that the enforcement setting ultimately may change the relative strengths. Lastly, in FIG 6, group policy objects that are to be enforced are shown with a parenthetical "(e)" therein, while blocking of suggested policy is shown by an "X

[Blocked] in the chain, e.g., between Domain A and OUI Beginning at step 760 of FRi. 7A, the lowest (closes) to the user) organizational unit in the hierarchy, organizational min DU2 for the user represented in FIG. 6 is selected. Step 702 determines if there is at least one group policy object at DU2's level, i.e., associated with the organizational unit QU2 to the present example of FIG. 6, four group policy objects (GPO3, GPO4, GPO5 and GPO6) are associated with the organizational unit OU2, whereby step 702 branches to step 704 where the highest ordered group policy object of this set, GPO3, is selected. Step 706 tests whether the selected group policy object GPO3 is to be enforced, (i.e., has its "No Override" option checked in the user interface), denoted in FIG. 6 by a parenthetical "(e)" above the arrow representing the association. Since GPO3 is entoreed at this level, step 708 is executed, which places an identifier of the selected group policy object GPO3 at the top of a temporary cuforce list 92, as shown in Flci 8A. As described below, the temporary enforce list will be used to construct the master (ordered) list 90 of group poticy objects for the user of users under OU2

Step 712 then tests if there is another group policy object at this level that has not yet been handled. As shown in FIG. 6, the group policy objects GPO4, GPO5 and GPO6 are also associated with OU2, and thus the step 714 selects the next-highest ordered group policy object, GPO4, before the process returns to step 708. The group policy object (5PO4 is not enforced, and thus this time step 706 branches to step 710 wherein the selected group policy object, GPO4, has an atentifier added therefor to the end of a temporary nonenforce list 94 (14G, 8B). As can be understood by following the steps 706-714, the other two group policy objects, GPO5 (coforced) and GPO6 (non-enforced) are placed into the temporary enforced list 92 and temporary non-enforced list 94, respectively, as shown in FIGS-8C and 8D. Note that via step 708, the GPO5 identifier is entered above the GPO3 identifier in the temporary enforced list 92.

When there are no more group policy objects at the B current level to place in the lists, step 712 branches to step 720 of FIG. 7B, where the group policy objects in the temporary enforce list 92 are moved to a master enforce list 96 as represented in FIG. 8E. The master enforce list 96 will accumulate the enforced group policy objects from the 18 various levels, and will ultimately be merged with a master non-enforce list 98 to construct the master list 90. Step 722 then tests it blocking has been selected at any level below the current level. If blocked, non-enforced group policy objects will not be applied. However, in the present example, there is no blocking selected, and thus step 722 branches to stop 724 where the group policy objects in the temporary non-enforce has 94 are moved to the from of a master non-enforce list 98 as represented in FIG. 8F. Step 728 then tests to determine if the current level is the appearmost level as example of FIG 6, is enforced, and is thus added by step 708 in the hierarchy of directory containers for the user, e.g., the site level. Since the current directory container is the orgamizational unit OU2, and not the site level, step 728 branches to step 730 which selects the next level up, i.e., the organiprocess then returns to step 702 of FIG. 7A.

At step 762, the properties of the organizational unit OUI are examined to determine if there is a group policy object associated therewith. Since in the present example of FIG. 6 there is not, step 702 branches to step 728 of FIG. 7B where its the site level is again tested for and found antrue. At slep 730 the process then selects the uest level up, the domain directory container, Domain A, and returns to step 702 of FIG. 7A to handle any group policy objects associated with the Domain A

As shown in FIG. 6, Domain A has three group policy objects associated therewith, GPO1, GPO2 and GPO3. As understood from the above description, slep 704 selects GPO1, step 706 determines that GPO1 is enforced, and thus Step 708 inserts GPOI into the temporary enforce list 92 as (FIG. 8G). Steps 712-714 select the next strongest group policy object, GPO2 (non enforced), after which steps 706 and 710 add a GPO2 eleutilies therefor to the temporary non-enforce list 94 (FIG. 811). Next, steps 712 and 714 select GPO3 (enforced), and steps 706 and 708 usert it at the lop of the temporary enforce list 92, as shown in FIG. 81.

See 720 of FIG. 7B next moves the GPO identifiers from the temporary enforce list 92 to the master enforce list 96. (FIG. 81). Note that as shown in FIG. 81, the master enforce list 96 is building (upwardly) the list of GPOs first by 25 hierarchy and then by strength within the hierarchy. Nonunforced policy is handled in an inverse hierarchical order, although the strength within the bicorchy is still maintained. This is in accord with the overall concept of having enforced policy at higher levels win versus policy at lower levels, so however lower-level policy wins over any higher level non-enforced (suggested) policy. In other words, a site-level administrator can thus enforce policy over a domain level administrator, who can enforce policy over administrators of organizational units below (also hierarchically ranked). 65 GPO2, GPO4, GPO4, GPO5, GPO3, GPO3, GPO3, GPO1 However, the lower-level administrators can discard any suggested policy from a higher level

Step 722 then determines that the non-enforced policy settings are blocked below Dontain A, (via OU1, e.g., there is a blocking flag set), as shown in PIG. 6 by the "X between Dontain A and OUL Blocking is directed to preventrag inheritance from non-enforced group policy objects associated with directory objects (sites, domains, and organizational units) above. As a result, there is no blocking on the same hierarchical level, i.e., GPO6 could not block GPO4. In general, this means that any non-enforced (supposted) policy above OU1 will be discarded. To accomplish this, step 722 branches to step 726 which clears the temporary non-enforced list 94, without adding any entries there is to the master non-enforced list 98, as shown in U.G. 8K. Note that bad OU2 blocked inheritance from its parent containers, Domain A's non-enforced policy objects, would similarly have been discarded, i.e., any blocking below a directory container blocks that directory container's associated group policy objects that are non-enforced, as well as any non-enforced group pulicy objects associated with higher-level directory communers. Step 728 again determines 20 that the process has not yet handled the group policy objects (if any) at the site level, and moves up in the bicearchy, this time selecting the site directory container \$1 at step 730.

As is understood from the above described steps, the site's associated group policy object, GPO4 in the present to the temporary enforce list 92 (FIG. 81.), and then moved by step 720 to the master enforce list 96 (FIG. 8M). This time, step 728 determines that the process has handled the GPOs for this user, i.e., has finished building the master anional unit OUI in the present example of FIG. 6. The 36 enforced list 96 and master non-culoiced list 98. Step 732 then merges the lists into the master list 90 by writing the weakest GPO identifiers from the left to the right in order of strength. Lastly, step 734 adds any local machine policy, as the least strongest policy (because by rule it cannot be cuforced) as shown in FIG. 9. To this extent, the local policy may be considered the top of the hierarchy, however it is not allowed to enforce, otherwise it would be the strongest policy, defeating the purpose of setting policy from a centralized location. Note that it is alternatively feasible to allow the local machine policy to be blocked, whereby in the present example the LGPO identifier would not be added to the master list 90 (FIG. 9) A higher policy setting may be used to control whether the local machine policy may be blocked or will be applied regardless of blocking. Further, note that it is also alternatively feasible to have the focal machine policy not be processed, by default, unless a higher policy allows the local mactione policy to be processed Multiple local machine policy objects, with an ordering among them, are also teaseble Local machine policy is particularly useful for standslone machines that are not part of a domain. Security descriptors (e.g., including Discretionary Access Control Lists, or DACLS), described below. in conjunction with local machine policies provide for different groups of users having different policies on standalone machines.

Thus, as expected from an analysis of FIG. 6, the site's enforced policy, GPO1, as strongest in the master ordered list 90, followed by the domain's enforced policy objects (GPO1, GPO3 as ranked by strength within that level). followed by OU2's enforced policy (GPO3, GPO5 as canked by strength within that level). The non-enforced policy is less strong, ordered as GPO4, GPD6. Note that alternatively, if there was no blocking selected, the order would have read from weakest to strongest, Local Machine polary object(s), At this time the ordered list 90 of policy objects is

complete, and the policies now may be applied to the user

or users of OO2 and/or the machine on which the user is logging on. It should be noted that the machine policies are applied to the machine when the machine operating system is booled, while the user group policies are applied when a user of the group logs on. In addition, group policy may be processed periodically, (a default time of unicly minutes, factoring in a thory-minute variable offset to distribute the notwork and server load, wherein both times may be changed by a policy), so that policy changes are undated on machines that are not frequently re-hooted and for overs that do not frequently log off

Once the ordered list 90 of policy objects is complete, at least one client extension 100 is typically called (e.g., by a desktop management engine 102, FIG. 2) and the list 90 provided thereto to be processed in any way the client-side a extension 100 deems appropriate. Indeed, because the group policy objects may contain virtually any type of information, and because the information therein and the list 90 may be used by a client extension 100 in any desired way, the system Typical examples of how the list 90 is used is to determine which scenary serongs apply to a user or machine, (e.g., access rights and/or group memberships), determine whether one or more user folders are sentirected to the network, and so on. Scripts may be processed according to 25 the ordered list 90, for example to apply policies that determine which applications will be contally deployed (assumed, published and/or installed) to users and machines of a network, as described in U.S. patent application Set. No. 00058 968

Another typical way in which policies are applied is to have at least some of the settings of the policy objects written to the registry of the user's machine. Applications and the like may then check the appropriate registry locations before taking curnin requested actions, in order to 14 perform or not perform the action according to the policy setting, (or some default value if no policy is defined for a particular setting) By way of example, FIG. 10 shows one way of placing paticy into a user's machine registry, using registry APIs for writing thereto. In general, a policy selting may be defined or not defined, and if defined, has some value for its setting. Phus, defined policies are written into the registry from weakest to strongest based on the ranked list 90 of group policy objects, whereby stronger group policy objects write defined policy settings over the settings of 49 weaker policies, i.e., last writer wins. To this end, at sten 1000, the weakest policy object in the list 90, i.e., the LGPO (local group policy object) is selected. Then, at step 1002, each registry-based setting that is defined is written in the registry. Step 1004 then tests to see if all the group policy objects have been handled, which at this time is not true, and thus step 1004 branches to step 1006 to select the next weakest group policy object, "GPO6" from the lot 90. Step 1886 then returns to step 1002 to write the defined settings of "GPO6" to the registry. The next weakest group policy " object, "GPO4" is selected at step 1006, which then returns to step 1002 to write the defined settings of "GPO4" to the registry, and so on, until the group policy objects in the list are handled. Note that undefined policy settings are not written, whereby any defined policy settings remain intact in the registry. Thus, for example, if GPO6 had an internet access policy bit setting of 1 (Allowed), and GPO4 had no opinion on internet access, then the "allowed" setting from GPO6 remains (unless subscentrally overwritten by defined GPO5, GPO3 or GPO1 policy). In this manner, policies are assumulated and combined in an ordering determined by the

administrators.

12

Still another way in which policy may be applied to a user is to maintain the ordered list 20 of group policy objects in association with a user/machine, and then walk through the list from strongest to weakest seeking a defined policy setting that satisfies a pending action request. For example, the various applications and settings therefor available to a group need not be written into the registry lot each user, but rather maintained in the group policy objects. If the user wishes to run an application, the process attempting to run the application uses the fist to first look to the strongest policy object to see if the action is allowed or denied, and if indefined, continues by querying the next strongest policy object in the list 90. The process will continue wilking through the list 90 uptil an answer (e.g., allow or deny) is obtained, or until there are no more policy objects in the led to query, at which time a default answer may be used.

Additional features of group policy objects are also pro vided to facilitate administrator control over their operation First, an association between a directory container and a and method of the present invention are highly extensible. 2a group policy object may be disabled, e.g., via an administrator selection (FIG. 5), whereby the group policy object is not applied to users for that particular directory container. However, this is not the same as removing the association of the group policy object with the container, because the group policy object still appears (in a disabled state) in a list of group policy objects seen by the administrator via the user

Another feature is that a group policy object includes both computer settings (HKFY LOCAL MACIENE) and user se (HKEY\_CURRENT USER) settings, which may be separately disabled. Such disables are global, i.e., they apply to all links thereto, whereby all users trader a directory container associated with the group policy object will not get the disabled portion or portions of the group policy object. For example, an administrator may disable the computer or user settings if either portion is not needed, providing a performanec improvement. Similarly, an administrator may use this type of disabling to debug a group policy object problem, e.g., by maning off one portion of the group policy object at a buse to determine which portion causes a prob-

The present invention also provides additional flexibility with respect to administering policy in a number of other ways. First, as described above, since group policy is maintained in objects, the containers may link to more than one group policy object and the group policy objects may be shared by multiple discency objects (containers), i.e., the same group policy object may be applied to multiple sites. domains/organizational units. For example, as shown in FIG. 11, user 80, receives policy from the chain A, B, C, D. in a hierarchical order with enforcement and blocking possable as described above. However, the user 80, under organizational unit 762 shares the group policy object 667 with organizational unit 76,, rather than having an ordependent group policy object defined therefor, whereby the user 80, receives policy from the chain A, B, Y, Z, which is effectively A. B. Y. D. Linking is valuable because it means only one set of policy settings needs to be maintained for possibly many groups of users under different hierarchies, e.g., a change to the setting of any group policy object is potentially implemented in multiple groups. For example, the sales related policy for an enterprise's Last Coast sales group may need to be the same as the policy for its West Coast sales group, however other non-sales policy may be different for the groups. Placing the sales-related polary into a shared group policy object ensures that the sales policy is consistent throughout the enterprise. Note that linking and associations with group policy objects may occur across a domain boundary as shown in FRG. 3, i.e., organizational unit B2 (764) is associated with the group policy object A5

(66.) Each policy object may also handle exception management in order to include or exclude certain users or groups of users from certain policy. To this end, each policy object may include an exclusion list of users and groups to which the policy will not apply and/or an inclusion list of users and groups to which the policy will apply. This is accomplished vis the security descriptor associated with each object. An administrator may specify which groups of users and computers have "Apply Group Policy" access control entries in the security descriptor to determine access to the group policy object. In general, groups that have Apply Group a Policy and read access to the group policy object receive the group policies therein, while groups that do not have Apply Group Policy or read access to the group policy object do not get the group policies therein. Note that security descriptors rights associated with each security identifier, and are capable of handling both metusion and exclusion. For example, within a research group, certain users may be given a different Internet access policy than other users, e.g., via the scentity descriptor, apply the policy to listed users A, 25 B and C, but no others in the group. Alternatively, via the scentity descriptor, the policy is applied to all users in the research group except X and Z who are specifically denied access to this policy object. This enables policy to be tailored to individual users without having to construct many separate groups to handle the various exceptions that typically arise in enterprises builder, policy may be enforced for certain users and suggested for other users by splitting a groups, policies into two groups, (e.g., Ac and A), and then using security access control to select which users in that is group get which policy

Another aspect of the present invention enables policy based on the machine's physical location, in addition to the user's logical function (reflected in the user's membership in various groups). In office words, policy may be made notwork topology aware. This is accomplished by associating a group pulsey object (e.g., 66.) with a site 72, as shown in FIG. 3. In this way, a user logging on in Europe may be given different policy settings than that same user logging on in the United States. The other aspects of the present invention, including layering (ordering), inheritance, blocking, linking and exception management are applicable to the group policy object or objects of a site, and thus a site's policy object or objects may fit anywhere within the ordered list.

The present invention also provides for an enterprise noticy, a policy that is applied to all domains. FIG. 12 shows a number of domains  $70_A$  -  $70_k$  under an enterprise 92. In this model, domains may be placed under the emerprise, whereby the policy senings of the enterprise are propagated 35 through the domains via inheritance. Moreover, as described above, a mumber of domains may share a group policy object to achieve a similar effect

Morcover, in keeping with the invention, the desktop management engine 192 (FIG. 2) may further facilitate the a use of moup policy objects by the chem side extensions 100, primarily to enhance performance. A first way in which performance may be enhanced is by separating the various chant-side extensions 100 by functionality (e.g., one for handling registry based settings, one for scripts, one for scentity policy settings and so forth), whereby each extension may receive a customized ordered list 90 listing only

1.1

those group policy objects that are relevant thereto. In other words, rather than generate only one ordered list 90, the desktop management engine 102 may generate a plurality of such lasts, one for each extension, each list customized, applied and maintained on a per-extension basis. For example, an extension may be interested only in security policy, whereby group policy objects that have no security pulsely therein need not be part of the ordered list received by that extension. An attribute in each of the group policy objects lists the extensions that have settings therein, whereby the desktop management engine 102 knows which of the extensions 102 are interested in which group policy objects, and each extension receives in its ordered list only those group policy objects that are tagged with that extension's identifying information.

The desktop monagement engine 102 monitors for various types of events and notifies appropriate extensions of those events, whereby the extensions 100 may reapply the policy. A first type of event occurs when some change is made to the suchide one or more security identifiers and a bitmask of 10 index of the group policy objects in the ordered list 90 with respect to each affected extension. For example, an admin istrator may remove (or add) a group policy object, whereby a new ordered list is generated for each extension. The new list is compared with the previous list for each extension to see if the list has changed for that extension, whereby the relevant extensions are separately called upon such a change, e.g., when policy is updated. To this end, the desktop management engine 102 saves the previous ordered list of group policy objects for each extension and compares it to the new list, taking into consideration which changes are relevant per extension.

By way of example, as shown in FRi. 13A, group policy object GPOB has been removed from a previous list GPOA, GPOB, GPOC, and GPOD, causing a new list of GPOA. GPOC, and GPOD. Each extension tagged in GPOB is then called with the change information (i.e., GPOB was deleted), and also passed the new list. The called extensions can get on this information, such as to do what is necessars to clear our GPOB's policy settings, and thereafter typically reapplies the new fist (GPOA, GPOC, GPOD), although theoretically, the extension need not reapply the new list if it was intelligent enough to know that GPOB had only some isolated policy settings. Note that dependencies among the group policy pineets may be changed, however, so policy according to the new hat is ordinarily reapplied.

To remove (or sild) a group policy object from a leat, the

administrator may not actually temove (or add) the group policy object from a container, but may effectively remove (or add) the group policy object (e.g., GPOB) with respect to an extension. For example, the administrator may multify all security settings from a group policy object, whereby that GPOB policy object is no longer relevant to the client-side. security extension and is removed from the ordered list (GPOA, GPOC and GPOD) received by the security exten sion. However, GPOB may still be relevant to other estensions such as script and registry extensions, whereby those extensions receive (al necessary) the full ordered list, GPOA. GPOB, GPOC, and GPOD. Another reason that a GPO may he removed from (or added to) a list is that an administrator may change a user's security rights. For example, an administrator may change a user's security rights such that the user no langer has access to a group policy object. In such an event, the group policy object a removed from each of the ordered less in which it is identified. Similarly, if seemily is changed to give a user access to a group policy object, that group poincy object is accumulated in new appropriatelyordered lists for the user

15

FIG. 13B shows, another type of change, wherein the administrator ronders the policy objects, e.g., 619OA, GPOB CPUC and GPOD to GPOA, GPOC, GPOH and GPOD Because of dependencies (e.g., among scripts) and other order-related schungs (e.g., lad writer wins in the Spirity schungs) as beschilder and the few min in the Spirity schungs is beschildered by the most aware of such a reordering, so that each other hand aware of such a reordering, so that each scheduler share are taged to object as the new order.

As represented in EIG, 13C, another change occurs when in the information in a group policy object changes, as tracked by a version monter. In FIG. 13C, in applied version of GPOB, GPOB, has been changed in version GPOB, and the extensions that deal with GPOB need to be called with the change information so that GPOB need to be called with the change information so that GPOB, is pulse, or possible to addition to the control of the control of the called and the need to the control of the control of the called some proceeding the group policy objects, the extensions represellate reapily the cuttle new blot

Another claims which extensions may register for not findation of a camages to group membership. In general, a whenever an administrator changes a need's membership in a group, e.g., by anatomy the member from a group or adding the member from a row group, the group policy do-shap management engine 102 calls each evention register of for infiliation of this type of change. Decision specified in the type of change is because which policy of the control of the control

Another forem that may be used to influence how group a bookly is applied in the rate which data may be transferred. For example, if a link is slow, then certain policy inflormation such as registry settlings, are applied, but ruller policy-related events such as sufficiare metallations are not applied because they would rule too long, i.e., if compliance are supported due to a slow link, the script extension may clear the sergins. More purchashrive, registry-bowed policies and seniority settlings are applied by default faint cannot be torough a sufficient policies are not an another policy which the register with Secretary Section 2 another policy whether the policy and another policy whether the health policy links and the policy whether the health policy links are more policy as the policy of the policy and the policy whether the health policy links and policy whether the health policy links are the policy and the polic

At each policy update, (which requests in IP connection) the data transfer rate, is evaluated, as described below. Whenever a change time a slew to fact or fost or slow than the six detected, a fost transition flag inflicating a change in the rate, along with a link rate flag fedow or firstly, are used to call appropriately explorated extensions to provide the inflormation needed to adjust for the late's data transfer rate of correct, a fine of solicious among rates may be provided so other than simply fact or slow, e.g., relatively small software installations may the place for including of such connections, but not over slow connections, bowever a straightforward distinction between first and the six of the six of

To determine, the connection rate, each client machine 19 generally follows the steps set forth in FIGS. 14A-14H.

First, at step 1440t, two variables, a forn cumter (Iry) and a transmission time counter (Irit), described below, as initialized to zero. Then, at step 1402, the domain controller is proposed over the link with in (recomb policy) of lank by the transports, is received at the client, step 1400 records the time, years a variable. The first 1540 pt 1400 records the time, years a variable. The client step 1400 records the time, years a variable. The client step 1400 records the time, years a variable time of the proposed of the response (normal tip) time, is rapid, e.g., less than ten millicecounts, then the connection is known to be find, whereby year 1440 branches of to step 1420 where the flags are adjusted as necessary and the process each. Extensions registered for link insusions.

16

may be called at this time, e.g., if the link was previously slow. Note that if the ping timed out without a response, this value is not valid and is discarded, e.g., the process branches ahead to step 1416 (not shown).

If al step 1406 a response was received and took former than ten millissecombs, there may be a unruled of reasons why the response was slow, including that the connection is slow, or that the domain controller was temporarily busy. Thus, rather than assume the connection is slow, an actual data stransfer rate is calculated, by looping up to their times, while discarding any clearly invalid values and averaging to balance any temporary anomalies. To this end, step 1406 branches to step 1408 where the domain controller is again pinged, this time with four kilobytes (40% bytes) of data. At sico 1410, the response time is recorded in a second variable. Time, (provided the ping did not time out, whereby the process would effectively diseatd this invalid value and also Tiple s, e.g., by branching ahead to step 1416, not shown) If the response time took less than ten milliseconds as deler mined at step 1412, then as described above, the connection is considered to be last, whereby step 1412 branches to step 1420 to adjust the link rate as necessary, after which the process is ended

If the response again took more than ten millisceouds, step 1412 branches to step 1414 where the difference between Time, and Times, Delta, is calculated and, if the tesult is valid, is added to a Total. Another example of an invalid result is one in which the result is negative, i.e., the four-kilobyte transfer time (Time,) was smaller than the zero data transfer time, (Time,). Because Time, corresponded to the time transfer no data, under ordinary circumstances Time, represents the time taken for overhead in the pany response operation. In an ordinary case, the overhead time will be the same for the subsequent "4K" ping/response operation, and thus Delta equals the time to transfer loan bilobytes of data after compensating for the overhead, However, as mentioned above, rather than calculate the data transfer rate from a single sample, an average is used, and thus step 1416 increments a loop counter and step 1418 evaluates whether the loop has been performed the desired number of times, (e.g., three). If not, step 1418 loops back to step 1402 where the transfer rate is again obtained. Note that while knoping, if at any time a response can come back in less than ten milliscentels, the connection is considered to be fast and the process is ended.

Once the Total time for the three lowe kildsive transfers of shounced, this information may be used to decremine wheeler the fink is fast or show. An administrator may set the adder versus Lest three-field, or a default included may be used (e.g., 500 kildsibst per second, i.e., 500 klop). Because it is designable to compass the actual kine transfer late with a threshold data transfer rate mander than is meaningful to an administrator, seep [430-4436 concern the Total name for a data transfer rate. In this trust way the transfer rate, I take took seep "Lovecur the Total name for a data transfer rate. In this trust way the transfer rate is the collection of the designation of the control of the control of the control of the section of the collection of the control of the section of the collection of the control of the section of the collection of the control of the section of the collection of the collection of the section of the collection of the collection of the section of the collection of the section of the collection of the collection of the collection of the section of the collection of the collection of the collection of the section of the collection of the collection of the collection of the section of the collection of the collection of the collection of the section of the collection of the collection of the collection of the section of the collection of the collection of the collection of the section of the collection of the collection of the collection of the section of the collection of the collection of the collection of the section of the collection of the collection of the collection of the section of the collection of the collection of the collection of the section of the collection of the collection of the collection of the section of the collection of the collection of the collection of the section of the collection of the collection of the collection of the section of the collection of the collection of

Once the incastired data marsfer rate (Z) is obtained, at sep 1438 the actual rate Z is compared agained a threshold rate, established by default or set by an administrator if below the rate, the link is considered slow (step 1440), while if above the rate, the link is considered slow (step 1440), while if above the rate, the link is considered fast (sep 1442), whereby the link transition and link rate buts are adjusted excordingly.

Still another teamer of the desktop management engine 102 enables group policy objects to be accumulated based on a machine's location in the hierarchy, instead of or in conjunction with the user's policy. By way of example, machines in a computer laboratory may need policy settings & that carefully control what is allowed to be done to those machines, regardless of which user is logging on. A machine policy setting in the registry determines how policy is to be applied, in one of three modes, the normal mode, in coninjuction with user policy, (merge mode), or instead of je user-based policy settings (replace mode)

14G. 15 shows an example of how policy is applied based on the mode setting, wherein users under organizational and OUT and machines under organizational unit OU2 are under DomainZ. As shown in FIG. 15, OUI has a group policy as object GPOD associated there with, OU2 has a group policy object GPOC associated therewith, and DomainZ has two group policy objects associated therewith, GPOA and GPOB. As described above, in the pormal node, the ordered and GPOD ffrom weakest to strongest assuming no enforcement for purposes of samplicity). If the machine indicates that more mode should be applied, two lists of ordered group policy objects will be obtained, first one for the user and then one for the machine. The machine's policy list of as ordered group policy objects is merged with the user's policy list by appending the machine policy list at the strong and of the mar notice list. Thus, the ordered list of group policy objects for the hierarchy in FIG. 15 when in merge mode will be accomplated as GPOA, GPOB, GPOD GPOA, 30 GPOR and GPOC. Lastly, when replace mode is set, the policy is simply the machine's policy list of ordered group policy objects instead of the user's policy list, GPOA, GPOB and GPOC

As can be seen from the foregoing detailed description, is there is provided a method and system for implementing policy by accommitating policies for a policy recipient, (e.g., computers or users) from policy objects associated with containers. Policy settings for the policy recipient may be accumulated by inheritance, enforced by directory objects, an blocked from being inherited, and layered in a specified order. I inking group policy objects is also provided, as is exception-based management.

While the invention is stocyptible to various modifications and alternative constructions, certain illustrated 48 embodiments thereof are shown in the drawings and have been described above in detail. It should be understood, however, that there is no intention to limit the invention to the specific form or forms disclosed, but on the contrary, the extention is to cover all modifications, alternative so constructions, and equivalents falling within the spirit and scope of the invention

What is obviousl is: 1. A method of determining policy to apply to a policy recipient under a plurality of liserarchically organized direction tory containers, wherein at loss one of the directory contamers is associated with at least one group policy object having policy information therein, comprising the steps of: selecting each directory container, and for each selected

directory container determining if any group policy object is associated with that directory container, and if so, for each

group policy object associated therewith determining if that group policy object is enforced. and if so, including an identifier of that group as

policy object in a list of group policy objects to apply to the policy recipient, and if not enforced.

determinance if that group policy object is blocked, and if not blocked, meltiding an ideatitier of that group pathey object in a list of group policy objects to apply to the policy regionant

2. The method of claim 1 further comprising the step of applying policy to the policy recipient based on the list of group palicy objects

3. The method of claim 1 wherein the list is ordered such that enforced group policy objects are stronger than nonenforced group policy objects.

4. The method of claim 1 further comprising the step of ordering the list such that enforced group policy objects are ranked according to the hierarchy of the directory containers, such that each enforced group policy object associated with each higher threctory container is stronger than each group policy object associated with each lower directory container.

5. The method of claim 1 further comprising the sten of ordering the list such that non-enforced group policy objects list will be that accumulated for the user, i.e., GPOA, GPOB, to are tanked according to the hierarchy of the directory containers, such that each non-enforced group policy object associated with each lower directory container is stronger than each non-enforced group policy object associated with each higher directory container

6. The method of claim 1 wherein at least one directory communer is associated with a planning of group policy objects, and further comprising the step of ranking the group policy objects associated with that directory container.

7 A computer-readable medium having computerexecutable instructions for performing steps comprising, placing policy scatteres into a planality of group policy objects, accumulating identifiers corresponding to the group policy objects into an ordered list, and providing the ordered list to an extension for applying the policy settings to a puliey recipient.

8. The computer-readable medium of claim 7 having further comparer executable abstructions for performing the steps of detecting a change related to policy

9. The computer-readable medium of claim 8 wherein the step of detecting a change related to policy comprises the step of, determining that a group policy object has been rentoved with respect to the extension, and having further computer-executable instructions for performing the step of, providing a new ordered list to the extension

10. The computer-readable medium of claim 9 wherein the step of determining that a group policy object has been removed with respect to the extension includes the step of detecting a change to access rights of a group policy object. 11. The computer-residable medium of claim 8 wherein the step of detecting a change related to policy comprises the son of, determining that a new group policy object has been added with respect to the extension, and having further computer-executable instructions for performing the step of, providing a new ordered list to the extension including an

identifier of the new group policy object 12. The computer-readable medium of claim 8 wherein the step of detecting a change related to policy comprises the step of, determining that group membership of a policy recipient has changed, and having further computer executable instructions for performing the step of notifying or the extension of a change in the group membership.

13. The computer readable medium of claim 8 wherein the step of detecting a change related to policy comprises the step of, determining that the group policy objects have been reordered, and having further computer-executable instructions for performing the step of, providing a new ordered list to the extension based on a new ordering of the group policy

### US 6,466,932 B1

19

- 14. The computer-consisted motion of chim 8 wherein the sept of detecting a change classed to notice comprises the steps of, detecting a change classed to notice comprises the steps of, detecting a monitor in a data transfer rate by a principum first pring response time, by quantity a selected 5 monitor of data and obtaining a second time corresponding to a second pury response time, and cy calculating the data transfer rate between the data of t
- 15 The computer-readable medium of claim 14 having, further computer-recentable instructions for performing the steps of, repressing steps a) and (b) at least one other time, and averaging the differences between each pair of valid second and first response times to obtain the value.
- 16. The computer-readable medium of claim 7 having further computer-executable instructions for part forming the step oil, determining which of a plurality of group policy objects to place in the ordered light based on a mode of a local medium.
- 17. The computer-readable medium of claim 16 wherein the mode inductors normal, and wherein the step of determining which of a plurality of group putery objects to place in the ordered list comprises the step of selecting group policy objects associated with containers of a user policy 25 constraint.
- 18. The computer residable medium of claim 16 wherein the most undersets merge, and wherein the step of determining wherein 2 plurating of group policy objects to place in the ordered het comprises the steps of selecting group policy objects associated with containers of a user policy recipient, and selecting group policy objects associated with containers of a user policy enditines of a marking policy textipient.
- 19. The compine-readable mailing of claim 16 wherein the mode indicates replace, and wherein the step of determining which of a plurality of group policy objects to place in the ordered list comprises the steps of selecting group policy objects associated with containers of a machine policy recipion.
- 20. The computer-readable medium of claim 7 having as further computer-executable instructions for performing the steps of, maintaining in the group policy objects a list of at least one extension having settings therein.
- 21. The computer readable medium of chim 20 having interfer computes, executable interactions for performing the se-Steps of, maintaining in the group publicy objects a list of at least inne exterior having settlings, therein, and wherein the chap of ensomment, the ordered list computes the steps of, for each group principality affect and extensive the steps of, for each group principality affect and extensive the steps of, office therein, and if so, noteding an akuniform of the group nobley object in the ordered list of the the extension.
- 22. The computer-readable medium of claim 7 wherein a plurality of extensions are present, and taving further computer-executable instructions for performing the steps 85 of, customizing the ordered that for each of the extensions.
- 23 The computer-readable medium of claim 7 having further computer-executable instructions for performing the see of periodically providing a new ordered list to the execusion.
- 24 A computer readable medium having computercoverable instructions for performing steps, comprising placing policy settings and a plurality of group policy objects;

#### 20

- accumulating the policy settings of the plurality of group policy objects, into accumulated policy, comprising, ordering the group policy objects, including developing a master list of ordered group policy objects;
- associating the accumulated pulsey with a policy recipient; and
- applying the accommlated policy to the policy recipiest by writing policy settings to a registry at an order determined by the master list.
- 25 A computer-readable medium having computer-executable instructions for performing steps, comprising placing policy settings into a phrabity of group policy objects.
  - accumulating the policy settings of the placetity of group policy objects into accumulated policy, comprising ordering the group policy objects, including developing a master hist of ordered group policy objects.
- associating the accumulated policy with a policy recipient, and
- applying the accumulated policy to the policy recipient by sacking settings in the group policy objects in an order determined by the master list.
- 26. A computer readable medium having computer executable instructions for performing steps, comprising
  - placing policy settings into a plurality of group policy objects;
- accumulating the policy settings of the plantily of group policy objects into accumulated policy, comprising ordering the going pulsy objects metability developing, a master list of ordered group order objects, wherein developing the morter test comprises, selecting a directtory container as a selected container, determining it a group policy object mosculated with the selected container is to be enforced, and if so, placing an admitter of that group policy object into an enforce bits, and
- associating the accumulated policy with a policy recipient.

  27. The computer-readable medium of claim 26, wherein
- 27. The computer-rectants meet an in crans an observed if the group polley object associated with the selected container is not enforced, developing a moder life compress, determining 18 blocking is set by a directory confirmer below the selected container, and if not, placing an identifier of that group polley object into a non-entroce list.
- 28. The computer-readable medium of claim 27 wherein developing a master list of indered group policy objects comprises, merging the enforce list and the non-enforce list.
- 29 A computer-stadable medium having computer-pleniable assumations for performing steps, comprising, pulsed and provided assumation of the performing steps, comprising, pulsed assumption of the policy acting of the plantility of group policy objects into accumulated policy, sessibility of the accumulated policy with a policy recipient, applying the accumulated policy with a policy recipient, applying the accumulated policy with a policy recipient of a discioner container, and excluding at least one otherwise chigale policy recipient flacefrom.
- 30. The computer-readable medium of claim 29 wherein seedading at least one otherwise clipible policy reaspent from the accumulated policy comprises modifying a security descriptor of the group policy objects.
